Background

Data

Conclusions

Background

Conflict and Fertility

- Armed conflicts crucially shapes individuals' long-term decisions, including **reproductive behavior**
- The legacy of conflict on reproductive behaviour has significant **long-term implications** in post-conflict settings:
 - Pop. growth and environmental threats, health risks, educational attainments and economic growth
- Women in conflict-affected areas should have **higher fertility rates** (Islam et al., 2016; Kraehnert et al., 2019)
 - low contraception use, low education, replace children lost to the conflict
- Yet, **the opposite is plausible** (Agadjanian and Prata, 2002; De Walque, 2006)
 - postpone childbearing; prioritize child “quality” over “quantity”
- We know little once **the conflict is settled and peace is being kept**

Post-Conflict and UN Peacekeeping

- UN has launched 70+ peacekeeping missions worldwide since 1960
- Today 70,000 blue helmets deployed in 12 missions around the world
- Peacekeeping **reduces violence** in ongoing wars and the probability of conflict recurrence (Hultman, Kathman and Shannon, 2013)
- It **improves households' well-being** by revitalizing economic exchanges and labor market participation and instilling confidence and trust (Bove, Di Salvatore and Elia, 2022)
- It **reduces maternal mortality rates** and increases maternal health and women's access to services and education (Gizelis and Cao, 2021)

Research Question: Fertility in Post-conflict Liberia

Does the provision of a secure environment through the deployment of UN peacekeepers affect fertility?

- Hosted one of the **largest UN peace operation**
- Has one of the **highest fertility rate** (4 kids per woman)
- Use individual survey data (DHS07;13;19) and geo-coded PK data in Liberia
- Reconstruct the **birth histories** and trace all children women have ever given birth
- **DV**: likelihood to have a child and # of children

The UN Mission in Liberia (UNMIL)

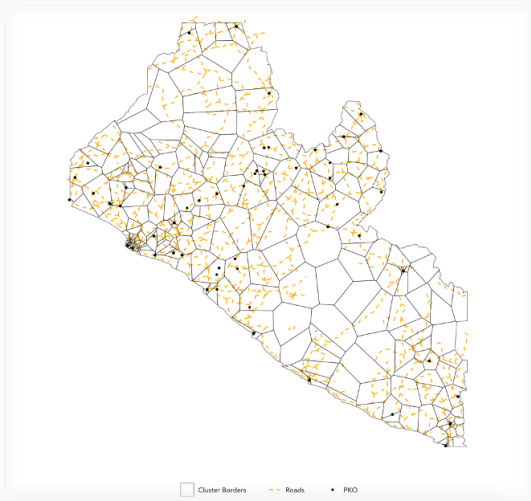

- UN peacekeepers **first deployed in 2003**, after two devastating civil wars from 1989 to 2003 and 250,000 people killed (Economist, 2022).
- The UN force consisted of 14,700 personnel in 2004 and reached the maximum strength in 2005 with 16,000+
- After 15 years of continuous deployment, the last 500 peacekeepers **left the country in 2018**
- **Multidimensional mission** aimed at supporting the peace process and humanitarian activities, and assisting in national security reforms
- Also **partnered with local organizations on development projects** to improve the lives of the local populations, providing public goods including medical services

Data

Data source

- We use three rounds of the **Liberian DHS (2007, 2013 and 2019)**, which provide respondents' geolocation (DHS cluster=village)
- We reconstruct the **full birth histories** and trace all children women have ever given birth **in the years before and after the UN arrival**
- These data are then matched with geocoded information on **UNMIL monthly subnational deployment** based on the GeoPKO dataset (Cil, Fjelde, Hultman, & Nilsson, 2020)
- GeoPKO provides the locations of deployment, from which we calculate the **road distance to each DHS cluster**
- As UNMIL mission moved across the country, we track its movement to correctly identify before- and after-deployment births

Road Network and PKO Location

Distance from PK Base

Respondents' location (*) and distance from PK base (o)

Where UN troops are deployed:

- Women's likelihood of having a child drops by 5 pp (6% of the mean)
- The total number of children per woman declines by 25% (13% of the mean)
- The effect varies across age groups, parity level and marital status

- **Mechanisms:** Effects explained by **improved parental investment on children (family planning) and less by opportunity cost of raising children.**

1. Quality-quantity tradeoff

- ↑ # antenatal visits
- ↑ iron intake
- ↑ birthweight
- ↑ baby postnatal checks
- ↓ under 5 mortality
- ↓ deliver at home

2. Opportunity cost

- No effect on employment
- No effect on women's decisions on earnings
- No effect on decisions on large purchase
- ↑ contraception use

Conclusions

Final Remarks

- We provide **first evidence of the local impact of UN peacekeeping** on fertility, looking at the case of the UN intervention in Liberia
- We find that UN has a significant and socially **meaningful impact on either margin of fertility**
- This effect seems to be explained by improved maternal health and childbirth outcomes as well as greater contraceptive use, consistent with the quality-over-quantity hypothesis
- Results suggest that the presence of peacekeepers, besides improving local security, can support better and more-informed **family planning** and improve **health condition of mothers and children**.

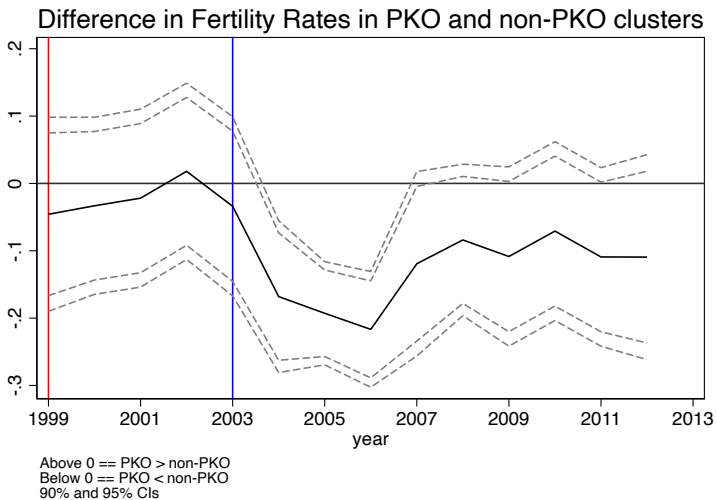

Empirical Strategy

- We estimate the following specification:

$$Y_{icjt} = \alpha + \beta PKO_i + \delta X_{it} + \gamma Z_c + \mu_j + \eta_t + \epsilon_{icjt} \quad (1)$$

- Y_{icjt} is a dummy = 1 if a woman i residing in cluster c located in district j and interviewed in wave t reports any birth since PK deployment in her cluster (or is the # of children)
- PKO_i measures peacekeepers presence within a 10km road distance from i 's cluster
- X_{it} is a set of individual characteristics, e.g., age, education, marital status, no. of children pre-PKO, etc.
- Z_c cluster-level factors, e.g., malaria prev, pop size, rainfall, proximity to water/borders, land aridity, econ activity, irrigation, livestock, avg time to reach a major settlement.
- μ_j and η_t are district and wave fixed effects

Fertility Trends Before and After UN Intervention

Pre-Deployment Violence (2001-2003) and PKO Location
